(Received 6 February 2003; published 11 July 2003)

New, radiatively generated, leading order (LO) quark (u, d, s, c, b) and gluon densities in a real, unpolarized photon are presented. We perform a global 3-parameter fit, based on LO Dokshitzer-Gribov-Lipatov-Altarelli-Parisi evolution equations, to all available data for the structure function $F_2^\gamma(x, Q^2)$. We adopt a new theoretical approach called ACOT(χ), originally introduced for the proton, to deal with the heavy-quark thresholds. This defines our basic model [Cornet-Jankowski-Krawczyk-Lorca (CJKL) model], which gives a very good description of the experimental data on $F_2^\gamma(x, Q^2)$, for both Q^2 and x dependences. For comparison we perform a standard fit using the fixed flavor-number scheme (FFNS_{CJKL} model), updated with respect to the previous fits of this type. We show the superiority of the CJKL fit over the FFNS_{CJKL} one and other LO fits to the $F_2^\gamma(x, Q^2)$ data. The CJKL model gives also the best description of the CERN LEP data on the Q^2 dependence of the F_2^γ , averaged over various x regions, and the $F_{2,c}^\gamma$, which were not used directly in the fit. Finally, a simple analytic parametrization of the resulting parton densities obtained with the CJKL model is given.

I. INTRODUCTION

The photon structure function was recognized as an important quantity already in the early days of the parton model [1]. It has attracted even more attention since the seminal paper by Witten [2], which shows that F_2^γ can serve as a unique test of QCD. This expectation was based on the fact that the (asymptotic) pointlike solution of the Q^2 evolution equation, summing the leading QCD corrections, can be obtained for F_2^γ without additional assumptions. Further studies showed the need of the hadronic, vector-meson-dominance (VMD)-type, contribution to F_2^γ , and consequently the need of an input, as for every other hadronic structure function.

The structure function F_2^γ is extracted from measurements in deep inelastic scattering on a photon target, which can be performed in e^+e^- experiments. The F_2^γ data are used to construct parametrizations of the parton distributions in the photon. The need for a resolved photon interaction, i.e. where a photon interacts via its partonic agents, has become apparent in other types of processes involving photons, namely, in the production of particles with a large transverse momentum. A recent review of the experimental situation and the existing parametrizations can be found in [3].

Our motivation for a new global analysis of the F_2^γ data and for constructing a new parton parametrization for a real unpolarized photon is twofold. On the one hand, there is a vast amount of new experimental data on $F_2^\gamma(x, Q^2)$ that has not been used yet to produce the parton parametrizations for the photon. Two recent parametrizations, by Glück, Reya, and Vogt (GRV) [4] and Glück, Reya, and Schienbein (GRS) [5], used respectively about 70 and 130 experimental points, while at present a total of 208 independent $F_2^\gamma(x, Q^2)$ points exist. On the other hand, there are discrepancies between the theoretical calculations and experimental results for some processes initiated by real photons in which heavy quarks are

produced [50]. Let us just mention here the D^* - and D_s -meson photoproduction [7], [8] and [9] or the D^* -meson production with associated dijets [7] at the DESY ep collider HERA, as examples. The disagreement between the theoretical and experimental results is even more profound for the open b -quark production in both HERA [10] and CERN e^+e^- collider LEP [11,12] measurements.

The idea of the radiatively generated parton distributions has been successfully introduced by the GRV group first to describe the parton distributions in the nucleon [13] and pion [14], and later to create the leading order (LO) and next LO (NLO) parton parametrization for the real [4] and virtual [15] photon. Here we follow this approach for a real photon case, limiting ourselves to the analysis based on the LO QCD. The NLO analysis is in preparation.

As mentioned above there is a problem with the QCD description of heavy-quark production in processes initiated by photons. Therefore, our analysis especially focuses on the heavy-quark contributions to the $F_2^\gamma(x, Q^2)$. A first attempt in this direction can be found at Ref. [16]. We apply a new variable flavor-number scheme (VFNS) approach, denoted by ACOT(χ) (Aivazis, Collins, Olness, and Tung) proposed for heavy-quark production in the ep collision ("electroproduction") in [17]. For comparison we perform a standard fixed flavor-number scheme (FFNS) fit as well. Since these two approaches are based on very distinct schemes, and since they need different evolution programs, we will refer to them as to two models, Cornet-Jankowski-Krawczyk-Lorca (CJKL) [ACOT(χ) type] and FFNS_{CJKL} models, respectively.

Our paper is divided into six parts. In Sec. II we describe various approaches including the ACOT(χ) scheme [17], applied to the production of heavy quarks in hadronic processes. Section III is devoted to the description of the F_2^γ in LO QCD, paying special attention to an implementation of the ACOT(χ) scheme in the calculation of the $F_2^\gamma(x, Q^2)$. In

Sec. IV a description of the two global fits performed by us is given. In particular, we present the solutions of the Dokshitzer-Gribov-Lipatov-Altarelli-Parisi (DGLAP) evolution in both models. We describe in detail the assumptions for the input parton densities. In the fifth section of the paper, the results of the global fits are discussed and compared with the data for the $F_2^\gamma(x, Q^2)$, and for the $F_2^\gamma(x, Q^2)$ averaged over various x -regions. A comparison with LEP data for $F_{2,c}^\gamma$ is presented in Sec. V as well. The summary of the paper and an outlook of work in progress can be found in Sec. VI. Finally, in the Appendix we give a simple parametrization of the CJKL (LO) parton distributions.

II. VARIOUS SCHEMES FOR A DESCRIPTION OF HEAVY-QUARK PRODUCTION: THE PROTON-TARGET CASE

In this section we describe various schemes, which are used in the calculation of the heavy-quark production in hadronic processes. There exist two standard schemes. In the FFNS, the light quarks (u , d and s) and the heavy ones (c and b) are treated on a different footing. The light ones are treated as being massless, and together with the gluons, are the only partons in the proton. The massive c - and b -quarks are produced in the hard subprocesses: they can only appear in the final state of the process. In the second scheme, the zero-mass variable flavor-number scheme (ZVFNS), when the characteristic hard scale of the process is larger than some threshold associated with a heavy quark, this quark is also considered as a massless parton in the proton, in addition to the three light quarks. In this way, the number of different types of quarks (flavors) that we treat as partons in the proton increases with the scale of the process.

For the deep inelastic scattering on the proton (DIS_{ep}), where the structure functions of the proton are measured, the condition for considering a heavy quark to be a parton of the proton is given by a simple (kinematic) threshold condition for the total energy in the γ^*p collision W , namely $W > 2m_h$ (from now on we will denote the heavy quarks by h). It defines the kinematically allowed region for the production of a heavy-quark pair. However, for the structure functions, e.g. $F_2^p(x, Q^2)$, and further for the parton densities $q^p(x, Q^2)$, not W but the virtuality of the probing photon Q^2 is considered to be a natural scale. In the inclusive production of heavy quarks, their transverse momentum or mass is often taken as a characteristic (hard) scale μ , where $\mu \gg \Lambda_{QCD}$, at which parton densities of the initial hadrons are probed. The two, massive and massless, approaches are considered to be reliable in different μ regions. The FFNS loses its descriptive power when $\mu \gg m_h$; on the other hand the ZVFNS does not seem appropriate if $\mu \approx m_h$. In order to achieve a prescription working in all hard scale regions, various schemes trying to combine the two approaches have been proposed. They have a generic name: variable flavor-number schemes (VFNSs). The first of such approaches was introduced by the ACOT group in [18]. Other groups, such as Thorne and Roberts (TR) [19], Buza, Matiounine, Smith, and van Neerven (BMSN) [20] or Chuvakin, Smith, and van Neerven (CSN) [21], created their own versions of the VFNS [51].

Let us discuss some aspects of the VFNS in more detail. The VFNS introduces the notion of “active quarks,” for which the condition $\mu > m_q$ is fulfilled. Such quarks can be treated as (massless) partons of the initial hadron(s). Light (u, d and s) quarks are always active because for them $\mu \gg \Lambda_{QCD} \gg m_q$. The heavy-quark densities vanish for $\mu \leq m_h$, otherwise they differ from zero like in the ZVFNS. For example, for the charm quark we see that at $\mu = m_c$ we turn from a three flavor-number scheme to a four flavor-number one. If N_f equals the number of active (massless) quarks, we define the N_f -FNS as one where the N_f first quarks are treated as light and the remaining quarks as heavy.

In calculations based on the VFNS we take into account the sum of all contributions, which would be included separately in the ZVFNS and FFNS. Such a procedure requires a proper subtraction of the double-counted contributions. Such contributions have the form of the large logarithms $\ln \mu^2$, and are already resummed in the density $q_h(x, \mu^2)$.

An important aspect of the VFNS is the behavior of the heavy-quark contributions in the threshold region. Let us discuss as an example the production of heavy quarks in DIS_{ep} . As was already mentioned, a heavy quark can be considered as a parton of the proton if the center of mass energy of the hard process is $W > 2m_h$. However, if we use μ^2 equal to Q^2 , where $Q^2 = W^2 x / (1 - x)$, and impose the threshold condition on μ^2 , then, for any Q^2 , it may happen (for small enough x) that $q_h(x, Q^2) = 0$ in the kinematically allowed region, i.e. for $W > 2m_h$. On the other hand, nonzero heavy-quark densities may appear in the kinematically forbidden region in the (x, Q^2) plane. Moreover, such conditions can lead to a very steep or even noncontinuous growth of the heavy-quark distributions at the threshold.

In general one should ensure that all the ZVFNSs and relevant subtraction terms smoothly vanish when $W \rightarrow 2m_h$. Then, the nonzero contributions should give only those terms which arise in the FFNS approach, since this approach should reliably describe the region $W \approx 2m_h$. Different threshold conditions were used in different analyses; in particular, the ACOT group proposed to use a variable μ^2 given by

$$\mu^2 = \begin{cases} m_h^2 + cQ^2(1 - m_h^2/Q^2)^n & \text{for } Q^2 > m_h^2, \\ m_h^2 & \text{for } Q^2 \leq m_h^2, \end{cases} \quad (1)$$

where $c = 0.5$ and $n = 2$ in [18]. Still, in their approach the heavy-quark densities satisfy the boundary condition at $Q^2 = m_h^2$

$$q_h(x, \mu^2) \begin{cases} = 0 & \text{for } \mu^2 = m_h^2 \quad (Q^2 \leq m_h^2), \\ \neq 0 & \text{for } \mu^2 > m_h^2 \quad (Q^2 > m_h^2). \end{cases} \quad (2)$$

Recently, a purely kinematic solution of the threshold-behavior problem has been found, on which the so-called ACOT(χ) scheme [17] is based. A new variable, $\chi_h \equiv x(1 + 4m_h^2/Q^2)$, has been introduced to replace the Bjorken x as an argument in the heavy-quark h density in the ZVFNS contributions. More details can be found in Sec. III.

Although the above discussion was focused on the proton case, the problems with the proper treatment of the heavy-quark thresholds in the parton distribution are very similar for any target. In this paper we adopt the ACOT(χ) scheme to the real photon case for the very first time.

III. DESCRIPTION OF F_2^γ IN THE ACOT(χ) SCHEME

In this section we first recall the basic facts related to the structure function $F_2^\gamma(x, Q^2)$ for the real photon. Then we introduce the ACOT(χ) approach for the photonic case.

A. The parton densities in the photon

The deep inelastic scattering on a real photon (DIS $_{e\gamma}$) allows us to measure the structure function F_2^γ , and also other structure functions, F_1^γ , F_L^γ , . . . , via the process

$$\gamma^* \gamma \rightarrow \text{hadrons}, \quad (3)$$

see [1–3]. In the parton model this is described at lowest order by the Bethe–Heitler (BH) process, $\gamma^* \gamma \rightarrow q\bar{q}$ (see Fig. 1).

In the leading logarithmic ($\ln Q^2$) approximation or, in short, in the leading order of QCD (LO QCD), the photon structure function $F_2^\gamma(x, Q^2)$ can be written in terms of quark (antiquark) densities $q_i^\gamma(\bar{q}_i^\gamma)$ as follows:

$$\frac{1}{x} F_2^\gamma(x, Q^2) = \sum_{i=1}^{N_f} e_i^2 (q_i^\gamma + \bar{q}_i^\gamma)(x, Q^2), \quad (4)$$

where N_f is the number of different quark flavors that can appear in the photon (“active quarks”). Note that $q_i^\gamma(x, Q^2) = \bar{q}_i^\gamma(x, Q^2)$.

The evolution of the parton densities with $\ln Q^2$ is governed by the inhomogeneous DGLAP equations. In LO we have for a quark (similarly for an antiquark) and a gluon density

$$\begin{aligned} \frac{dq_i^\gamma(x, Q^2)}{d \ln Q^2} = & \frac{\alpha}{2\pi} e_i^2 k(x) + \frac{\alpha_s(Q^2)}{2\pi} \int_x^1 \frac{dy}{y} \left[P_{qq}\left(\frac{x}{y}\right) q_i^\gamma(y, Q^2) \right. \\ & \left. + P_{qG}\left(\frac{x}{y}\right) G^\gamma(y, Q^2) \right], \end{aligned} \quad (5)$$

FIG. 1. The Bethe–Heitler process $\gamma^* \gamma \rightarrow q\bar{q}$.

$$\begin{aligned} \frac{dG^\gamma(x, Q^2)}{d \ln Q^2} = & \frac{\alpha_s(Q^2)}{2\pi} \int_x^1 \frac{dy}{y} \left[P_{Gq}\left(\frac{x}{y}\right) \sum_{i=1}^{N_f} (q_i^\gamma + \bar{q}_i^\gamma)(y, Q^2) \right. \\ & \left. + P_{GG}\left(\frac{x}{y}\right) G^\gamma(y, Q^2) \right]. \end{aligned} \quad (6)$$

The $k(x)$ term on the right-hand side of Eq. (5) comes from the Bethe–Heitler process of Fig. 1; for 3 colors we have

$$k(x) = 3[x^2 + (1-x)^2]. \quad (7)$$

The functions $P_i(x)$ are the LO splitting functions [23]

$$\begin{aligned} P_{qq}(x) &= \frac{4}{3} \left[\frac{1+x^2}{(1-x)_+} + \frac{3}{2} \delta(1-x) \right], \\ P_{qG}(x) &= \frac{1}{2} [x^2 + (1-x)^2], \\ P_{Gq}(x) &= \frac{4}{3} \frac{1+(1-x)^2}{x}, \\ P_{GG}(x) &= 6 \left[\frac{x}{(1-x)_+} + \frac{1-x}{x} + x(1-x) \right] \\ &+ \left[\frac{11}{2} - \frac{N_f}{3} \right] \delta(1-x). \end{aligned} \quad (8)$$

Note that the function $k(x)$ describes a photon into quark splitting, so one has $k(x) \equiv P_{q\gamma}(x)$.

1. Heavy-quark contributions to F_2^γ in the FFNS

The standard FFNS approach corresponds to a number of “active quarks” ($N_f = 3$), so only the light quarks (and their antiquarks) are taken into account in the sum in Eq. (4). The main heavy-quark contributions to F_2^γ are obtained in this scheme from the corresponding Bethe–Heitler process (Fig. 1 with $q \rightarrow h$)

$$\gamma^* \gamma \rightarrow h\bar{h}, \quad (9)$$

keeping the heavy-quark masses in the calculation. It reads

$$\frac{1}{x} F_{2,h}^\gamma(x, Q^2)|_{\text{dir}} = 3 \frac{\alpha}{\pi} e_h^4 \omega(x, Q^2), \quad (10)$$

with

$$\begin{aligned} \omega(x, Q^2) = & \beta \left[-1 + 8x(1-x) - x(1-x) \frac{4m_h^2}{Q^2} \right] + \ln \left(\frac{1+\beta}{1-\beta} \right) \\ & \times \left[x^2 + (1-x)^2 + x(1-3x) \frac{4m_h^2}{Q^2} - x^2 \frac{8m_h^4}{Q^4} \right], \end{aligned} \quad (11)$$

$$\beta = \sqrt{1 - \frac{4m_h^2 x}{(1-x)Q^2}} = \sqrt{1 - \frac{4m_h^2}{W^2}}. \quad (12)$$

We call this contribution $F_{2,h}^\gamma|_{\text{dir}}$ since here the real photon (i.e., the target photon) interacts directly. However, there exists another heavy-quark contribution, related this time to the process with the resolved initial photon, namely

$$\gamma^* G^\gamma \rightarrow h\bar{h}, \quad (13)$$

with a gluonic parton of the photon target (as in Fig. 1 with $\gamma \rightarrow G^\gamma$); it gives

$$F_{2,h}^\gamma(x, Q^2)|_{\text{res}} = \frac{\alpha_s(Q^2)}{2\pi} e_h^2 \int_{\chi_h}^1 \frac{x}{z} \omega\left(\frac{x}{z}, Q^2\right) G^\gamma(z, Q^2) dz, \quad (14)$$

where

$$\chi_h \equiv x \left(1 + \frac{4m_h^2}{Q^2} \right). \quad (15)$$

2. Heavy-quark contributions to F_2^γ in the ZVFNS

In the ZVFNS, the number of “active quarks” changes with the hard scale, as described in the previous section. For low scales the sum in Eq. (4) extends to $N_f=3$ but whenever a heavy quark threshold is surpassed the value of N_f is increased by 1. It is worth mentioning that in some parton parametrizations for a real photon the heavy-quark densities do appear; however, they are described in the threshold region $W \approx 2m_h$ only by the above Bethe–Heitler formula [Eqs. (10) and (11)]. Moreover, instead of the restriction on W one sometimes takes a (reasonable) condition on Q^2 [see, for instance, the Gordon-Storow (GS) parametrization [24]]. Of course well above a heavy-quark threshold, such a quark can be included among the active (massless) quarks and then $N_f \rightarrow N_f + 1$, see [14].

B. ACOT(χ) scheme for F_2^γ

The ACOT(χ) prescription combines the FFNS and ZVFNS, so that we have to add all relevant contributions from both approaches. For the light-quark contributions we take the form given in Eq. (4) with $N_f=3$, while for the heavy quarks we include the following terms:

$$\begin{aligned} \bar{F}_2^\gamma(x, Q^2)|_{c,b} = & \sum_{h(c,b)}^2 [x e_h^2 (q_h^\gamma + \bar{q}_h^\gamma)(x, Q^2) \\ & + F_{2,h}^\gamma(x, Q^2)|_{\text{dir}} + F_{2,h}^\gamma(x, Q^2)|_{\text{res}}], \end{aligned} \quad (16)$$

where $F_{2,h}^\gamma(x, Q^2)|_{\text{dir}}$ and $F_{2,h}^\gamma(x, Q^2)|_{\text{res}}$ are given in Eqs. (10) and (14), respectively.

In Eq. (16) we double-count some heavy-quark contributions. Indeed, part of the $F_{2,h}^\gamma|_{\text{dir}}$ contribution from $\gamma^* \gamma \rightarrow h\bar{h}$ corresponds to the collinear configuration. Such a configuration leads to a contribution proportional to $\ln Q^2$ and is already included in the DGLAP equation for $q_h^\gamma(x, Q^2)$, via the $k(x)$ term. Therefore we must subtract from Eq. (16) the following terms:

$$F_{2,h}^\gamma|_{\text{dir,subtr}} = x \ln \frac{Q^2}{m_h^2} 3 e_h^4 \frac{\alpha}{\pi} (x^2 + (1-x)^2), \quad (17)$$

coming from an exact solution of a part of the DGLAP equation, namely,

$$\frac{dq_h(x, Q^2)}{d \ln Q^2} = \frac{\alpha}{2\pi} e_h^2 k(x), \quad (18)$$

integrated over the Q^2 from m_h^2 to Q^2 .

Similarly, $F_{2,h}^\gamma|_{\text{res}}$ from the $\gamma^* G^\gamma \rightarrow h\bar{h}$ process has a $\ln Q^2$ part that corresponds to the collinear configuration already included in the DGLAP equation for $q_h^\gamma(x, Q^2)$, via the $P_{qG}(x/y) G^\gamma(y, Q^2)$ term. The term to be subtracted reads, in this case

$$\begin{aligned} F_{2,h}^\gamma|_{\text{res,subtr}} = & x \ln \left(\frac{Q^2}{m_h^2} \right) e_h^2 \frac{\alpha_s(Q^2)}{\pi} \\ & \times \int_x^1 \frac{dy}{y} P_{qG}\left(\frac{x}{y}\right) G^\gamma(y, Q^2). \end{aligned} \quad (19)$$

It is based on an approximated solution for the other part of Eq. (5): namely,

$$\frac{dq_h^\gamma(x, Q^2)}{d \ln Q^2} = \frac{\alpha_s(Q^2)}{2\pi} \int_x^1 \frac{dy}{y} \left[P_{qG}\left(\frac{x}{y}\right) G^\gamma(y, Q^2) \right]. \quad (20)$$

The solution (19) is obtained by the integration of Eq. (20) over the same Q^2 region as above, after neglecting the Q^2 dependence [25] of α_s and G^γ . The final subtraction term is

$$F_2^\gamma(x, Q^2)|_{\text{subtr};c,b} = \sum_{h(c,b)}^2 [F_{2,h}^\gamma|_{\text{dir,subtr}} + F_{2,h}^\gamma|_{\text{res,subtr}}]. \quad (21)$$

So, finally we have, for heavy-quarks: $F_2^\gamma(x, Q^2)|_{c,b} = \bar{F}_2^\gamma(x, Q^2)|_{c,b} - F_2^\gamma(x, Q^2)|_{\text{subtr};c,b}$. A graphical representation of all terms included in the analysis, Eqs. (16) and (21), is presented in Fig. 2.

Further, we need to ensure that all terms containing the heavy-quark h disappear when $W \rightarrow 2m_h$. The FFNS contributions, $F_{2,h}^\gamma|_{\text{dir}}$ [Eqs. (10)–(12)] and $F_{2,h}^\gamma|_{\text{res}}$ [Eqs. (14), (15)], behave properly at the thresholds. The problem emerges for the heavy-quark densities q_h^γ and the subtraction terms [Eqs. (17), (19)]. These terms do not naturally disappear for $W \rightarrow 2m_h$. Fortunately, this problem can be cured; we noticed that the resolved-photon contribution in Eq. (14) vanishes for $W \rightarrow 2m_h$ because then $\chi_h \rightarrow 1$ and the corresponding integral disappears. So, we can do the same with the q_h^γ distribution and the subtraction terms, if instead of x we introduce the χ_h variable [Eq. (15)] slightly shifted from x . This way we force the heavy-quark distribution and the second term of the subtraction contribution (the integral term) to vanish at the corresponding threshold. Unfortunately, unlike for the proton, in the case of the photon we are left with the $F_{2,h}^\gamma|_{\text{dir,subtr}}$ con-

FIG. 2. Graphical representation of the ACOT model for F_2^γ . The first diagram represents the ZVFNS contribution. The third (fifth) diagram shows the FFNS contribution of the resolved (direct) photon, while the second (fourth) diagram is the corresponding subtraction term.

tribution, which is now proportional to $\chi_h^2 + (1 - \chi_h)^2$ and does not vanish for $\chi_h \rightarrow 1$. In the large- Q^2 region, where the ZVFNS is reliable, this change of variables is irrelevant. In the numerical calculations we ensure that the total contributions to F_2^γ due to heavy quarks are not negative (positivity constraint). This way we effectively introduce small additional terms near the c - and b -quark thresholds. The final formula for the in the ACOT(χ) scheme reads [26]

$$F_2^\gamma(x, Q^2) = \sum_{i=1}^3 x e_i^2 (q_i^\gamma + \bar{q}_i^\gamma)(x, Q^2) + \sum_{h=(c,b)}^2 x e_h^2 (q_h^\gamma + \bar{q}_h^\gamma) \times (\chi_h, Q^2) + \sum_{h=(c,b)}^2 [F_{2,h}^\gamma(x, Q^2)|_{\text{dir}} + F_{2,h}^\gamma(x, Q^2)|_{\text{res}}] - \sum_{h=(c,b)}^2 x \ln \frac{Q^2}{m_h^2} \left[e_h^4 \frac{\alpha}{\pi} k(\chi_h) + e_h^2 \frac{\alpha_s(Q^2)}{\pi} \int_{\chi_h}^1 \frac{dy}{y} P_{qG}\left(\frac{\chi_h}{y}\right) G^\gamma(y, Q^2) \right]. \quad (22)$$

As can be seen the heavy-quark distributions are included in the second sum as $q_h^\gamma(\chi_h, Q^2)$, being χ_h functions of x (and Q^2). We parametrize the final form obtained for these distributions in the Appendix as simple functions of x and Q^2 [27].

The χ_h variables of the ACOT(χ) scheme recall the so-called “slow rescaling” obtained in early papers on the charm-quark production in the DIS_{ep} (e.g. [28]), where the Bjorken x was replaced with ζ :

$$x \rightarrow \zeta = x \left(1 + \frac{m_c^2}{Q^2} \right). \quad (23)$$

IV. GLOBAL FITS: SOLVING THE DGLAP EVOLUTION

Using all the existing $F_2^\gamma(x, Q^2)$ data we perform two global fits, both based on the LO DGLAP evolution equations. One fit uses the ACOT(χ), the other a FFNS model for the heavy-quark contributions.

First we introduce the basic ingredients that are common for the two considered models.

A. Mellin moments

The LO DGLAP evolution equations are very much simplified if they are transformed into the Mellin-moments space. The n th moment for the quark or gluon densities, f_i^γ , is defined by

$$f_i^{\gamma,n}(Q^2) = \int_0^1 x^{n-1} f_i^\gamma(x, Q^2) dx. \quad (24)$$

Analogous definitions can be used for the splitting functions P_{ij}^n . The evolution equations in the Mellin space have the generic form

$$\frac{df_i^{\gamma,n}(Q^2)}{d \ln Q^2} = \frac{\alpha}{2\pi} k_i^n + \frac{\alpha_s(Q^2)}{2\pi} P_{ij}^n f_j^{\gamma,n}(Q^2). \quad (25)$$

Obviously, the first term on the right-hand side appears only for the quark densities. For simplicity, in the following we will skip all subscripts and superscripts wherever possible.

B. Nonsinglet and singlet parton densities

To solve the DGLAP equations we need to decompose the parton densities into the singlet and nonsinglet (in flavor space) combinations. For the nonsinglet (ns) case we have

$$f_{\text{ns}_{N_f}}^\gamma(Q^2) = \sum_{i=1}^{N_f} (e_i^2 - \langle e^2 \rangle) [q_i^\gamma(Q^2) + \bar{q}_i^\gamma(Q^2)],$$

$$k_{\text{ns}_{N_f}} = 2N_f (\langle e^4 \rangle - \langle e^2 \rangle^2) k \quad (26)$$

where

$$\langle e^k \rangle = N_f^{-1} \sum_{i=1}^{N_f} e_i^k \quad (27)$$

and e_i stands for the corresponding quark electric charge. Similarly for the singlet (s) densities we have

$$f_s^\gamma(Q^2) = \left[\begin{array}{c} \Sigma^\gamma(Q^2) \\ G^\gamma(Q^2) \end{array} \right],$$

$$\Sigma^\gamma(Q^2) = \sum_{i=1}^{N_f} [q_i^\gamma(Q^2) + \bar{q}_i^\gamma(Q^2)]. \quad (28)$$

In the singlet case the DGLAP equations (25) become a matrix equation with

$$\hat{P} = \begin{bmatrix} P_{qq} & 2N_f P_{qG} \\ P_{Gq} & P_{GG} \end{bmatrix}, \quad \hat{k} = \begin{bmatrix} k_s \\ 0 \end{bmatrix} \quad (29)$$

with

$$k_s = 2N_f \langle e^2 \rangle k. \quad (30)$$

C. Pointlike and hadronlike parts

The solution of the DGLAP equations can be divided into the so-called pointlike (pl) part, related to a special solution of the full inhomogeneous equation and hadronlike (had) part, arising as a general solution of the homogeneous equation. Their sum gives the partonic density in the photon, so we have

$$f^\gamma(Q^2) = f_{\text{had}}^\gamma(Q^2) + f_{\text{pl}}^\gamma(Q^2) \quad (31)$$

where

$$f_{\text{pl}}^\gamma(Q^2) = \frac{4\pi}{\alpha_s(Q^2)} \frac{1}{1-2P/\beta_0} \frac{\alpha}{2\pi\beta_0} [1 - L^{1-2P/\beta_0}] k, \quad (32)$$

$$f_{\text{had}}^\gamma(Q^2) = L^{-2P/\beta_0} f^\gamma(Q_0^2).$$

Here $\beta_0 = 11 - 2N_f/3$, P equals $P_{qq}(\hat{P})$ for the nonsinglet (singlet) parton densities, and

$$L = \frac{\alpha_s(Q^2)}{\alpha_s(Q_0^2)},$$

where the Q_0^2 is the evolution starting (input) scale. Note that at $Q^2 = Q_0^2$ the point-like part vanishes.

D. Input parton densities. Vector meson dominance

Following [4], the input scale has been chosen to be small, $Q_0^2 = 0.25 \text{ GeV}^2$, hence our parton densities are radiatively generated. The pointlike contributions are given by Eq. (30), while the hadronic parts need the input distributions. For this purpose we utilize the vector meson dominance (VMD) model [29], where

$$f_{\text{had}}^\gamma(x, Q_0^2) = \sum_V \frac{4\pi\alpha}{\hat{f}_V^2} f^V(x, Q_0^2), \quad (33)$$

with the sum running over all light vector mesons (V) into which the photon can fluctuate. The parameters \hat{f}_V^2 can be extracted from the experimental data on the $\Gamma(V \rightarrow e^+e^-)$ width. In practice one takes into account the ρ^0 meson [30] and the contributions from other mesons are accounted for via a parameter κ , which is left as a free parameter. We take

$$f_{\text{had}}^\gamma(x, Q_0^2) = \kappa \frac{4\pi\alpha}{\hat{f}_\rho^2} f^\rho(x, Q_0^2). \quad (34)$$

In the GRV prescription [4] the parton densities in the ρ^0 meson are approximated by the pionic ones: $f^\rho(x, Q_0^2)$

$\approx f^\pi(x, Q_0^2)$. However, this assumption ignores among others the possible effects of the pseudo-Goldstone boson nature of the pion, and we are not using it in our analysis [32]. Instead we use the input densities of the ρ^0 meson at $Q_0^2 = 0.25 \text{ GeV}^2$ in the form of valencelike distributions both for the (light) quark (v^ρ) and gluon (G^ρ) densities. All sea-quark distributions (denoted by ζ^ρ) are neglected at the input scale. At this scale, the densities v^ρ , G^ρ and ζ^ρ are related, according to Eq. (34) to the corresponding densities for a photon; see below.

The v^ρ density is given by

$$v^\rho(x, Q_0^2) = \frac{1}{4} (u^{\rho+} + \bar{u}^{\rho-} + d^{\rho-} + \bar{d}^{\rho+})(x, Q_0^2), \quad (35)$$

where from the isospin symmetry

$$u^{\rho+}(x, Q_0^2) = \bar{u}^{\rho-}(x, Q_0^2) = d^{\rho-}(x, Q_0^2) = \bar{d}^{\rho+}(x, Q_0^2). \quad (36)$$

Note that all the densities in Eq. (35) are normalized to 1, $\int_0^1 u^{\rho+} dx = 1$.

The following constraints should hold for the $v^\rho(x, Q_0^2)$ density. The first is related to a number of valence quarks in the ρ^0 meson, and we have

$$\int_0^1 2v^\rho(x, Q_0^2) dx = 2. \quad (37)$$

The second constraint represents the energy-momentum sum rule

$$\int_0^1 x(2v^\rho(x, Q_0^2) + G^\rho(x, Q_0^2)) dx = 1. \quad (38)$$

We parametrize the input densities as follows:

$$x\zeta^\rho(x, Q_0^2) = 0, \quad (39)$$

$$xv^\rho(x, Q_0^2) = N_v x^\alpha (1-x)^\beta, \quad (40)$$

$$xG^\rho(x, Q_0^2) = \tilde{N}_g x v^\rho(x, Q_0^2) = N_g x^\alpha (1-x)^\beta, \quad (41)$$

where $N_g = \tilde{N}_g N_v$, and impose two constraints given by Eqs. (37) and (38) in both models. These constraints allow us to express the normalization factors N_v and N_g as functions of α , β and κ . This leaves these three parameters as the only free parameters to be fixed in the fits to the F_2^γ experimental data.

E. FFNS_{CJKL} model

In the FFNS_{CJKL} model the number of “active quarks” (N_f) equals 3, so $\langle e^2 \rangle = 2/9$.

To describe the hadronlike part of the solution of DGLAP equations for the photon, we introduce, apart from the valencelike quark and gluon densities, also the sea distribution $\zeta_{\text{had}}^\gamma(x, Q^2)$. The up-, down- and strange-quark densities in the photon are then given by the following combinations:

TABLE I. The χ^2 for 208 points and parameters of the fits for FFNS_{CJKL} and CJKL models.

Model	χ^2	χ^2/DOF	κ	α	β	N_v	\tilde{N}_g
FFNS _{CJKL}	471	2.30	$1.726^{+0.076}_{-0.072}$	$0.465^{+0.071}_{-0.067}$	$0.127^{+0.197}_{-0.173}$	0.504	1.384
CJKL	430	2.10	$1.097^{+0.058}_{-0.053}$	$0.876^{+0.150}_{-0.132}$	$2.403^{+0.743}_{-0.623}$	2.644	2.882

$$u_{\text{had}}^\gamma(x, Q^2) = d_{\text{had}}^\gamma(x, Q^2)$$

$$= \frac{1}{2} [v_{\text{had}}^\gamma(x, Q^2) + 2\zeta_{\text{had}}^\gamma(x, Q^2)], \quad (42)$$

$$s_{\text{had}}^\gamma(x, Q^2) = \zeta_{\text{had}}^\gamma(x, Q^2). \quad (43)$$

From Eqs. (26) and (28) we get (below we simply use f_{ns}^γ instead of $f_{\text{ns}_3}^\gamma$):

$$f_{\text{ns, had}}^\gamma(x, Q^2) = \frac{1}{9} v_{\text{had}}^\gamma(x, Q^2), \quad (44)$$

$$\Sigma_{\text{had}}^\gamma(x, Q^2) = 2v_{\text{had}}^\gamma(x, Q^2) + 6\zeta_{\text{had}}^\gamma(x, Q^2). \quad (45)$$

After performing the DGLAP evolution of $f_{\text{ns, had}}^\gamma(x, Q^2)$ and $\Sigma_{\text{had}}^\gamma(x, Q^2)$ from Q_0^2 to higher Q^2 , we calculate $v_{\text{had}}^\gamma(x, Q^2)$ and $\zeta_{\text{had}}^\gamma(x, Q^2)$. Finally, using formulas (42) and (43), we obtain the hadronlike part for the individual quark densities.

As the down- and strange-quarks have equal electric charges, there are only two different pointlike distributions: $u_{\text{pl}}^\gamma(x, Q^2)$ and $d_{\text{pl}}^\gamma(x, Q^2) = s_{\text{pl}}^\gamma(x, Q^2)$. We calculate them again through the evolution of the singlet and nonsinglet combinations of the parton densities. It can be easily checked that distributions read as

$$u_{\text{pl}}^\gamma(x, Q^2) = \frac{1}{6} [\Sigma_{\text{pl}}^\gamma(x, Q^2) + 9f_{\text{ns, pl}}^\gamma(x, Q^2)],$$

$$d_{\text{pl}}^\gamma(x, Q^2) = \frac{1}{12} [2\Sigma_{\text{pl}}^\gamma(x, Q^2) - 9f_{\text{ns, pl}}^\gamma(x, Q^2)]. \quad (46)$$

Finally, the contribution due to the massive c - and b -quarks are approximated by the Bethe–Heitler formula (10)–(12) for $Q^2 > 4m_h^2$.

F. CJKL model

In the CJKL model all terms originating from both FFNS and ZVFNS are included. This means that apart from the light-quark distributions we take into consideration $c^\gamma(x, Q^2)$ and $b^\gamma(x, Q^2)$, which emerge in the ZVFNS, so here $N_f = 5$.

When five “active quarks” are considered instead of three, the DGLAP evolution becomes slightly more complicated and we need more nonsinglet parton densities than for the simple FFNS model. Here we need $f_{\text{ns}_2}^\gamma$, $f_{\text{ns}_3}^\gamma$, $f_{\text{ns}_4}^\gamma$, and $f_{\text{ns}_5}^\gamma$ [Eq. (26)] for both hadronlike and pointlike parts; using them and Σ , calculated for $N_f = 5$, we can express individual

quark densities [34] as follows:

$$u^\gamma = \frac{1}{20} (+45f_{\text{ns}_3}^\gamma - 30f_{\text{ns}_4}^\gamma + 15f_{\text{ns}_5}^\gamma + 2\Sigma^\gamma),$$

$$d^\gamma = \frac{1}{20} (-60f_{\text{ns}_2}^\gamma + 45f_{\text{ns}_3}^\gamma - 30f_{\text{ns}_4}^\gamma + 15f_{\text{ns}_5}^\gamma + 2\Sigma^\gamma),$$

$$s^\gamma = \frac{1}{20} (+60f_{\text{ns}_2}^\gamma - 45f_{\text{ns}_3}^\gamma - 30f_{\text{ns}_4}^\gamma + 15f_{\text{ns}_5}^\gamma + 2\Sigma^\gamma), \quad (47)$$

$$c^\gamma = \frac{1}{20} (-45f_{\text{ns}_3}^\gamma + 30f_{\text{ns}_4}^\gamma + 15f_{\text{ns}_5}^\gamma + 2\Sigma^\gamma),$$

$$b^\gamma = \frac{1}{10} (+30f_{\text{ns}_4}^\gamma - 30f_{\text{ns}_5}^\gamma + \Sigma^\gamma).$$

For the hadronlike parts we consider, similarly to the FFNS case, the light-quarks densities are given by Eq. (42). Among sea quarks we have now all types of quarks, in particular we have

$$s_{\text{had}}^\gamma(x, Q^2) = c_{\text{had}}^\gamma(x, Q^2) = b_{\text{had}}^\gamma(x, Q^2) = \zeta_{\text{had}}^\gamma(x, Q^2). \quad (48)$$

This leads to the following relations:

$$f_{\text{ns}_2, \text{had}}^\gamma = f_{\text{ns}_4, \text{had}}^\gamma = 0,$$

$$f_{\text{ns}_3, \text{had}}^\gamma = \frac{1}{9} v_{\text{had}}^\gamma, \quad (49)$$

TABLE II. Comparison of χ^2 values obtained for the FFNS_{CJKL} and CJKL fits to the $F_2^\gamma(x, Q^2)$ data with χ^2 calculated using the SaS1D and GRS parametrizations.

Model	No. of independent parameters	No. of data points			
		205		182-no TPC	
		χ^2	χ^2/DOF	χ^2	χ^2/DOF
SaS1D	6	657	3.30	611	3.47
GRS LO	0	499	2.43	366	2.01
FFNS _{CJKL}	3	442	2.19	357	1.99
CJKL	3	406	2.01	323	1.80

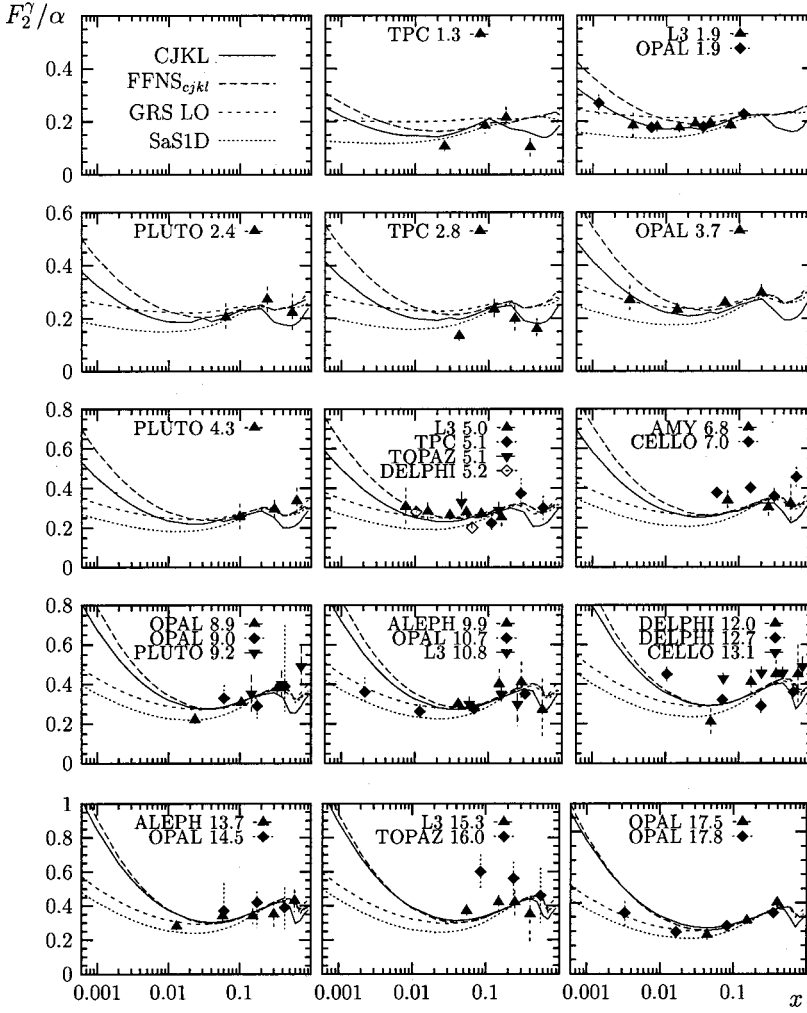

FIG. 3. Predictions for the $F_2^\gamma(x, Q^2)/\alpha$ for the CJKL and $FFNS_{CJKL}$ models and GRS LO [5] and SaSID [52] parametrizations compared with the experimental data [35–46], for small and medium Q^2 as a function of x (logarithmic scale). If a few values of Q^2 are displayed in the panel, the average of the smallest and biggest Q^2 was taken in the computation.

$$f_{ns_5, \text{had}}^\gamma = \frac{1}{15} v_{\text{had}}^\gamma$$

valid at every x and Q^2 .

In the pointlike case equality of the electric charges for the up-type and down-type quarks leads to the following relations: $u_{\text{pl}}^\gamma(x, Q^2) = c_{\text{pl}}^\gamma(x, Q^2)$ and $d_{\text{pl}}^\gamma(x, Q^2) = s_{\text{pl}}^\gamma(x, Q^2) = b_{\text{pl}}^\gamma(x, Q^2)$.

In our analysis, performed within the ACOT(χ) scheme, we evolve first the singlet and nonsinglet distributions and we obtain in this way the gluon $g(x, Q^2)$ and light-quarks $u, d, s(x, Q^2)$ densities. In each heavy-quark density, for c and b quarks, we replace the x variable by the corresponding χ_h variable; let us recall that $\chi_h = x(1 + 4m_h^2/Q^2)$, with m_h equal to m_c and m_b , respectively. For such densities we perform DGLAP evolutions and obtain the resulting $c(\chi_h, Q^2)$ and $b(\chi_h, Q^2)$ distributions. We then compute the $F_2^\gamma(x, Q^2)$ using Eq. (22) and fit the parameters of the model to the experimental data, which is described in more detail in the next section.

Finally, we parametrize all our resulting parton distributions analytically with the possibly simple functions of x and Q^2 . This parametrization is given in the Appendix.

V. GLOBAL FITS AND RESULTS

We have performed two fits to all the available $F_2^\gamma(x, Q^2)$ data [35–46]. All together, 208 data points were used, including the recent high- Q^2 measurement of the OPAL collaboration [46]. Although some of the data points are not in agreement with others we have included all of them as published by the experimental collaborations, without weighting them nor discarding any data set. We will discuss in detail the influence in the fit of neglecting the data from the TPC/2 γ Collaboration in the next section. The fits based on the least-squares principle (minimum of χ^2) were done using MINUIT [47]. Systematic and statistical errors on data points were added in quadrature.

The α_s value used in the fits was calculated from the LO formula, which depends on N_f

$$\alpha_s(Q^2)^{(N_f)} = \frac{4\pi}{\beta_0 \ln(Q^2/\Lambda^{(N_f)})} \quad \text{with} \quad \beta_0 = 11 - \frac{2}{3}N_f. \quad (50)$$

For $N_f=4$ we took the QCD scale $\Lambda^{(4)}$ equal to 280 MeV [48] with the assumption that the LO and NLO Λ values for four active flavors are equal, which is consistent with the

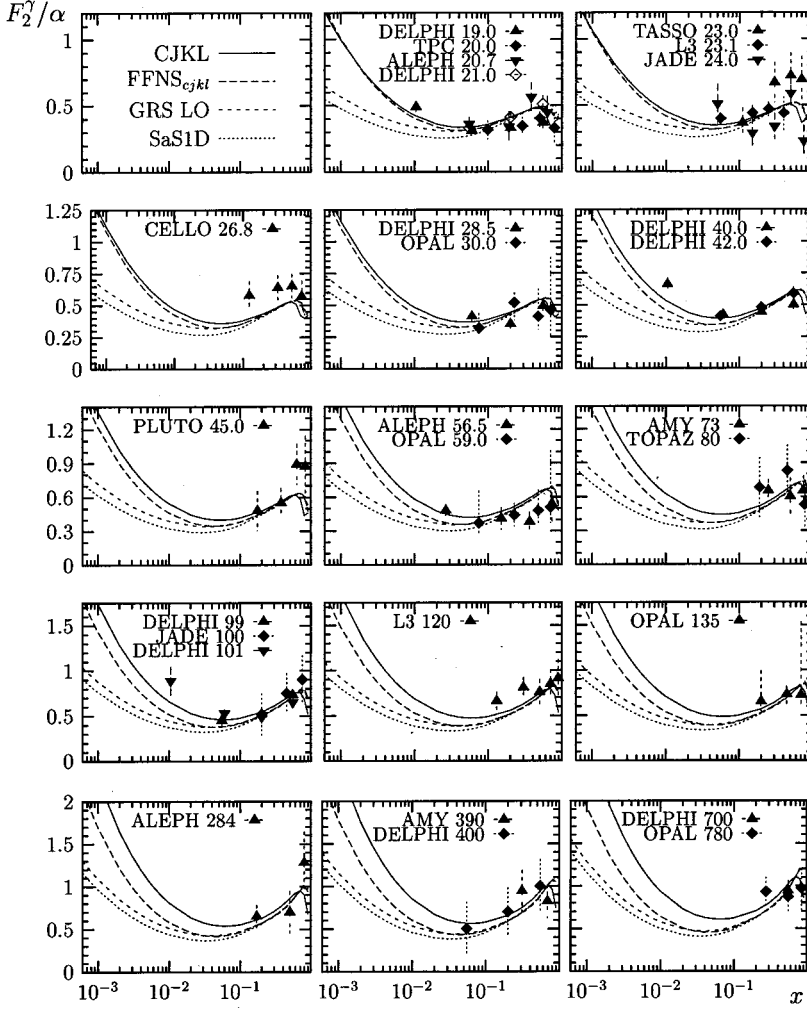

FIG. 4. The same as in Fig. 3, for $Q^2 \geq 20 \text{ GeV}^2$.

GRV group approach [4]. Values of Λ for other N_f can be calculated if one assumes a continuity of α_s at the heavy-quark thresholds $Q^2 = m_h^2$. Assuming then that $\alpha_s(m_h^2)^{(N_f)} = \alpha_s(m_h^2)^{(N_f+1)}$ one obtains the relation

$$\Lambda^{(N_f+1)} = m_h (\Lambda^{(N_f)} / m_h)^{(33-2N_f)/(31-2N_f)}, \quad (51)$$

which gives $\Lambda^{(3)} = 314 \text{ MeV}$ and $\Lambda^{(5)} = 221 \text{ MeV}$. Finally, the masses of the heavy quarks are taken to be [48]: $m_c = 1.3 \text{ GeV}$ and $m_b = 4.3 \text{ GeV}$.

The results of both fits are presented in Table I. The second and third columns show the quality of the fits, i.e. the total χ^2 for 208 points and the χ^2 per degree of freedom. The fitted values for parameters α , β and κ are presented in the middle of the table with the errors obtained from MINOS requiring $\Delta\chi^2 = 1$. In addition, the values for N_v and \tilde{N}_g obtained from these parameters using the constraints (37) and (38) are given in the last two columns.

We see that the obtained χ^2 per degree of freedom is better in the CJKL model than in the standard-type FFNS approach; however, it is not particularly good, owing to the poor quality of some data used in the analyses. This fact has been already discussed in many papers, [49], see also the discussion in Sec. V A.

The two fits to the same collection of data, although not very different as far as χ^2 is concerned, are obtained with very different sets of parameters. Note that κ is close to 1 in the CJKL case, while for the other fit it is closer to 2. If this parameter is close to 1, we have in practice only the ρ contribution at the input scale. However, this is not the whole story since the κN_v and κN_g give full normalizations of the valencelike quark and gluon densities in the γ . Now, the N_v and \tilde{N}_g are much smaller in the standard approach than in the CJKL model. Finally, let us notice the large difference in both models, at small and large x , of the fitted input densities, which correspond to very different α and β parameters, respectively. The FFNS_{CJKL} model has α close to the standard (Regge) one for a valence-quark density ($\alpha - 1 \sim -0.5$); however, its β , which governs the large- x behavior, is very small, being far from 2, a standard prediction from the quark-counting rule [33]. On the other hand, the CJKL model gives β closer to 2, while its $\alpha - 1$ is close to zero.

A. Comparison of the CJKL and FFNS_{CJKL} fits with F_2^γ data and other LO parametrizations

The χ^2 values, representing the quality of our LO fits, are compared in Table II with the corresponding χ^2 obtained by

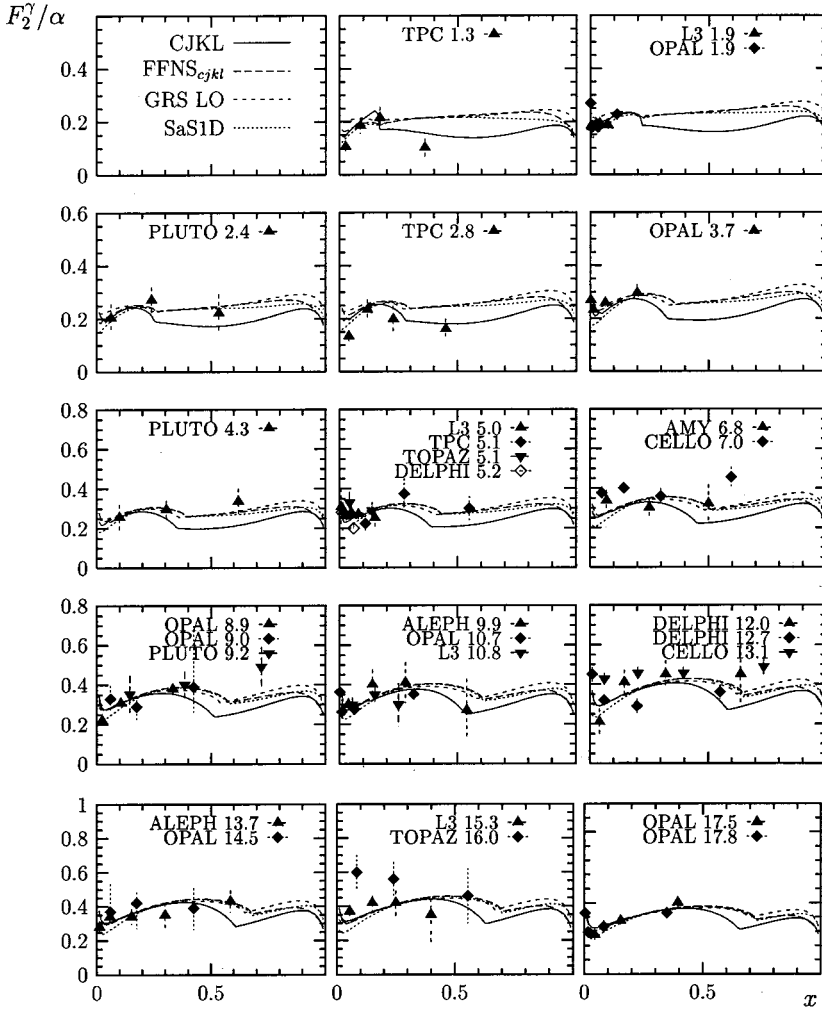

FIG. 5. The same as in Fig. 3 for a linear scale in x .

us using the GRS LO [5] and Schuler and Sjöstrand (SaS1D) [52] parametrizations to describe the present F_2^γ data. The comparison is performed for a set of 205 data points, i.e. excluding the points with $Q^2 < 0.26 \text{ GeV}^2$ since they were not used in performing the GRS parametrization. The second column gives the number of independent parameters in each model. The overall χ^2 and χ^2/DOF values are given in the middle of the table for 205 data points. It is clear that both our fits give a better description of the experimental data than the previous parametrizations. This could be expected since we are including more data in our fits. The CJKL model gives the lowest value of χ^2/DOF , but it is still rather high. This may arise from the fact that we use all available data and, as it was stated ([49]), the data published by the TPC/ 2γ Collaboration [38] are inconsistent with other measurements. We studied this point and in the last two columns of the table we present the χ^2 values calculated without the TPC/ 2γ points. Indeed the χ^2/DOF then computed is visibly improved [53]. A special CJKL fit performed without TPC/ 2γ data gives χ^2/DOF equal to 1.78. The very recent NLO analysis performed in [49] for 134 experimental points and with five independent parameters gives $\chi^2/\text{DOF}=0.93$.

Figures 3–6 show a comparison of the CJKL and $\text{FFNS}_{\text{CJKL}}$ fits to $F_2^\gamma(x, Q^2)$ with the experimental data as a

function of x , for different values of Q^2 . Also a comparison with the GRS LO and SaS1D parametrizations is shown. (If a few values of Q^2 are displayed in a panel, the average of the smallest and biggest one was taken in the computation.) As can be seen in Figs. 3 and 4, both CJKL and $\text{FFNS}_{\text{CJKL}}$ models predict a much steeper behavior of the $F_2^\gamma(x, Q^2)$ at small x with respect to other parametrizations. In the region of $x \geq 0.1$, the behavior of the $F_2^\gamma(x, Q^2)$ obtained from the $\text{FFNS}_{\text{CJKL}}$ fit is similar to the ones predicted by the GRS LO and SaS1D parametrizations. The CJKL model gives a lower prediction whenever the c -quark threshold is surpassed, and slightly below this region, as is shown in Figs. 5 and 6.

Apart from this direct comparison with the photon structure-function data, we perform another comparison, this time with LEP data that were not used directly in our analysis. Figures 7 and 8 present the predictions for $F_2^\gamma(x, Q^2)$, averaged over various x regions, compared with the recent OPAL data [46]. For comparison, the results from the GRS LO and SaS1D parametrizations are shown as well. We observe that all models give very similar predictions, which are in fairly good agreement with the experimental data. Only the CJKL model slightly differs from the other models considered: it gives better agreement with the data. The difference between the predictions of the CJKL model and the

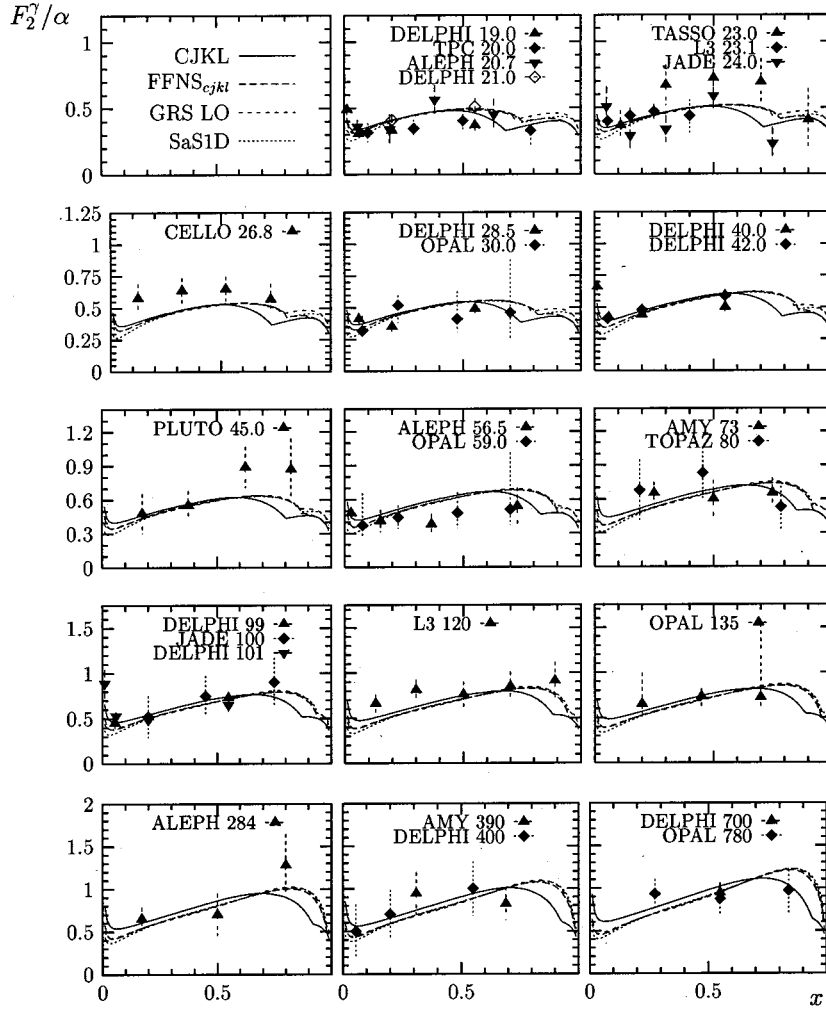

FIG. 6. The same as in Fig. 4 for a linear scale in x .

FIG. 7. Comparison of the recent OPAL data [46] for the Q^2 -dependence of the averaged over $0.1 < x < 0.6$ F_2^γ/α with the predictions of the CJKL and FFNS_{CJKL} models and GRS LO [5] and SaSID [52] parametrizations.

FIG. 8. As in Fig. 7 for $F_2^\gamma(x, Q^2)/\alpha$, averaged over four different x ranges.

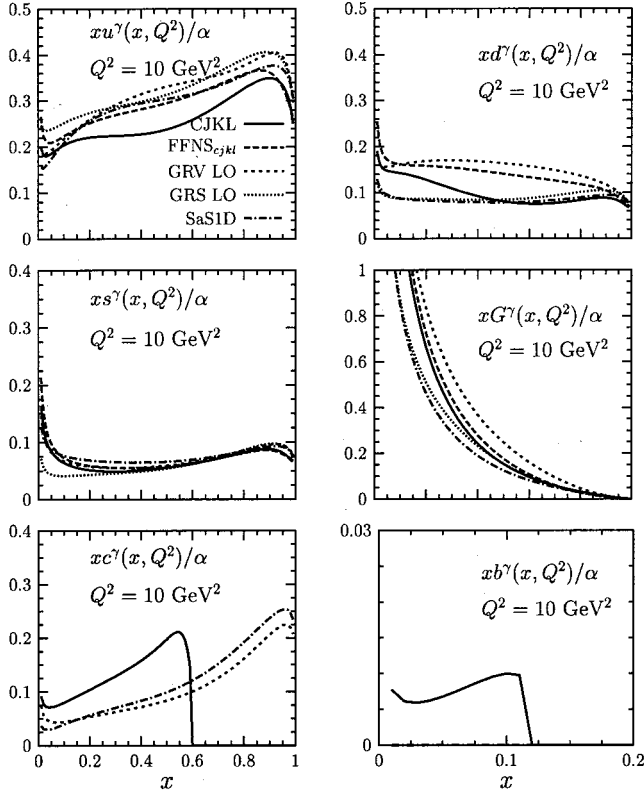

FIG. 9. Comparison of the parton densities predicted by various parametrizations at $Q^2 = 10 \text{ GeV}^2$, as a function of x . The c - and bottom-quark distributions of the CJKL model are compared with the only other predictions for heavy-quark densities among the parametrizations used (given by the GRV LO and SaS1D parametrizations).

other models is most striking in the case of the medium- x range, $0.1 < x < 0.6$ shown in Fig. 7. The CJKL curve clearly shows a departure from the simple $\ln Q^2$ dependence. This is caused by the additional Q^2 dependence due to the χ variable. The highest x range, $0.85 < x < 0.98$ (see Fig. 8) is the second region of a significant difference between the predictions of the CJKL and other models. The predictions split at high- Q^2 values, as the CJKL predicts a much softer Q^2 dependence.

B. Parton densities

In this section we present the parton densities obtained from the CJKL and FFNS_{CJKL} fits and compare them with the corresponding distributions of the GRV LO [4], GRS LO and SaS1D parametrizations. First, we present all parton densities at $Q^2 = 10 \text{ GeV}^2$ (Fig. 9). The biggest difference between our CJKL model and others is observed, as expected, for the heavy-quark distributions. Unlike for the GRV LO and SaS1D parametrizations, the densities $c^\gamma(x, Q^2)$ and $b^\gamma(x, Q^2)$ vanish not at $x=1$ but, as it should be, at the kinematical threshold. Also the up-quark density differs among models. In the CJKL model it is lower than in other parametrizations for $x > 0.1$. The same can be seen in Fig. 10, where for various Q^2 values the up-quark distributions are presented. The up-quark density in the CJKL,

FIG. 10. Comparison of the up-quark distribution at four values of Q^2 in the CJKL and FFNS_{CJKL} models with the GRV LO [4], GRS LO [5] and SaS1D [52] densities.

FFNS_{CJKL} and GRV LO models have similar behavior at very small x . The hardest up-quark distribution is obtained in the FFNS_{CJKL} approach, while both the GRS LO and SaS1D predictions are much softer. The same holds in the case of the gluon distribution, shown in Fig. 11. Finally, the charm-quark densities of the CJKL model and of the GRV LO and

FIG. 11. The same as in Fig. 10 for the gluon density.

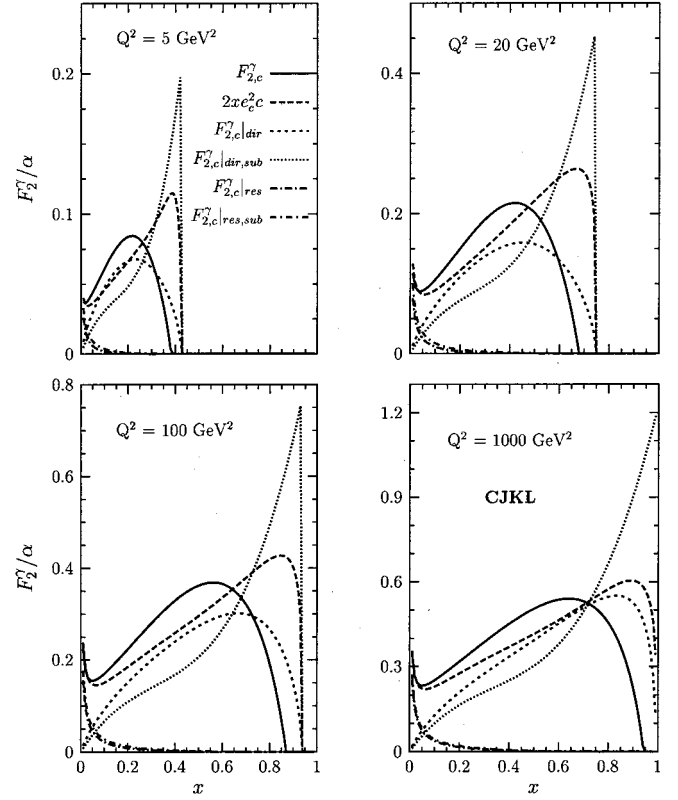

FIG. 12. The same as in Fig. 10 for the c -quark density.

GRS LO parametrizations are presented in Fig. 12. Here we see that, in addition to the already mentioned vanishing at the threshold, the charm-quark distribution in the CJKL model is larger than the ones in the other parametrizations. This is particularly true for larger values of Q^2 , where the threshold is very close to $x=1$.

Finally, in Fig. 13 we present our predictions for the $F_{2,c}^\gamma$. For $Q^2=5, 20, 100$ and 1000 GeV^2 we compare the individual contributions included in the CJKL model. As was explained in detail in Sec. III B, they all, apart from the $F_{2,c}^{\gamma|_{\text{subtr,dir}}}$ term, vanish in the $W \rightarrow 2m_c$ threshold. This term dominates near the highest kinematically allowed x . The direct BH term is important in the medium- x range. Its shape resembles the valence-type distribution. The c -quark density contribution, i.e., the term $2xe_c^2 c^\gamma(x, Q^2)$, is important in the whole kinematically available x range; it dominates the $F_{2,c}^\gamma$ for small x . In this region also the resolved-photon contributions increase, but they cancel each other.

C. Comparison with $F_{2,c}^\gamma$

A good test of the c -quark contributions is provided by the OPAL measurement of the $F_{2,c}^\gamma$, obtained from the inclusive production of $D^{*\pm}$ mesons in photon-photon collisions [54]. The averaged $F_{2,c}^\gamma$ has been determined in the two x bins. These data points are compared to the predictions of the CJKL and FFNS_{CJKL} models as well as with the SaS1D and GRS LO parametrizations in Fig. 14. The prediction of the FFNS_{CJKL} model, which as the only one among those compared does not contain the resolved-photon contribution, is based on the pointlike (Bethe-Heitler) contribution for heavy quarks only. As seen in the figure it decreases too quickly with the decreasing x , much faster than the predictions from other parametrizations. The CJKL model seems to give the

FIG. 13. Comparison of various contributions to the photon structure function $F_{2,c}^\gamma(x, Q^2)/\alpha$ in the CJKL model for $Q^2 = 5, 20, 100$ and 1000 GeV^2 .

best description of the data for the low- x bin, but overshoots the experimental point at high x .

VI. SUMMARY AND OUTLOOK

A new analysis of the radiatively generated parton distributions in the real photon based on the LO DGLAP equations is presented. All available experimental data have been used to perform two global, 3-parameter fits. Our main

FIG. 14. Comparison of the structure function $F_{2,c}^\gamma(x, Q^2)/\alpha$ calculated in the CJKL, FFNS_{CJKL} models and SaS1D [52] and GRS LO [5] parametrizations with the OPAL measurement [54].

model (CJKL) is based on a new variable flavor-number scheme [ACOT(χ)], applied to the photon case for the very first time. It has a proper threshold behavior of the heavy-quark contributions. The CJKL-model results are compared with an updated fixed flavor-number scheme (FFNS_{CJKL}) fit and to predictions of the GRS LO and SaSID parametrizations. Our model gives the best χ^2 of those compared. It describes very well the Q^2 evolution of the $F_2^\gamma(x, Q^2)$, averaged over various x regions. We have checked that the CJKL fit agrees also reasonably well with the prediction of a sum rule for the photon, described in [55].

We have also checked that the gluon densities of both CJKL and FFNS_{CJKL} models agree with the H1 measurement of the gluon density (G^γ) performed at $Q^2 = 74 \text{ GeV}^2$ [56]. In both models gluon densities are very similar to the gluon density provided by the GRV LO parametrization, which gave so far the best agreement with the H1 data. Further comparison of our gluon densities to the H1 data cannot be performed in a fully consistent way [57], since GRV LO proton and photon parametrization were used in the experiment in order to extract such gluon density.

One of the motivations for this work was given by the disagreement between the theoretical and experimental results for the open b -quark production in two-photon processes in the LEP [11,12] measurements. We did calculate the LO cross-section for c - and b -quark production in $\gamma\gamma$ collisions in the ACOT(χ) and FFNS schemes, using the CJKL and FFNS_{CJKL} distributions of partons, respectively. The cross-section for the c -quark production computed in both models agrees with the experimental data. The ACOT(χ) model gives a slightly better shape of the c -quark distribution. There is a small difference between the results of the two models for b -quark production. We observe an increase of the cross-section for the b -quark in the ACOT(χ) approach, as compared to the FFNS result, based on GRS LO parametrization, but it is too small to fit the experimental data. More work on this subject is required. Also, before reaching a definitive conclusion the NLO corrections should be considered and the NLO parton densities for the photon applied. The NLO parametrization in the CJKL model, together with the effects of different subtraction terms and positivity constraints, will be presented in a future publication.

A simple analytic parametrization of the results of our CJKL model for the individual parton densities is given, and a FORTRAN program calculating parton densities as well as the structure function F_2^γ [Eq. (22)] can be obtained from the web sites given in [59].

ACKNOWLEDGMENTS

M.K. thanks Wu-ki Tung for fruitful discussions, which led to this analysis, and R. Roberts for a discussion on the parton densities in the ρ -meson. P.J. would like to thank R. Taylor, M. Wing and all members of the Warsaw TESLA group for discussions. We are grateful to Rohini Godbole for useful suggestions on the parton-parametrization program and Mariusz Przybycień for discussions. This work was partly supported by the European Community's Human Po-

tential Program under contract HPRN-CT-2000-00149 Physics at Collider and HPRN-CT-2002-00311 EURIDICE. F.C. also acknowledges partial financial support by MCYT under contract FPA2000-1558 and Junta de Andalucía group FQM 101. M.K. is grateful for partial support by Polish Committee for Research 2P03B05119 and 5P03B12120.

APPENDIX: PARTON PARAMETRIZATION FOR THE CJKL MODEL

We give here an analytic form for the parametrization of the CJKL results for the individual parton densities. Following the GRV group we parametrize them in terms of

$$s \equiv \ln \frac{\ln[Q^2/(0.221 \text{ GeV})^2]}{\ln[Q_0^2/(0.221 \text{ GeV})^2]} \quad (\text{A1})$$

with $Q_0^2 = 0.25 \text{ GeV}^2$. The parametrization has been performed in the $10^{-5} < x < 1$ and $1 < Q^2 < 2 \times 10^5 \text{ GeV}^2$ ranges. We made a separate parametrization of the pointlike and hadronlike densities. The parametrized distributions of the light (u, d, s) quarks are in agreement with the ones obtained in the fit up to a few percent accuracy. The same is true for the gluon density, apart from the high- x region (where G_γ values fall down), where 10% accuracy is assured. We checked that the heavy-quark densities, for c - and b -quarks, are represented by our parametrization at 10% accuracy for $Q^2 \geq 2 \text{ GeV}^2$ and 10 GeV^2 , respectively. For both quarks those Q^2 values are below their masses squared $m_h^2 = 1.3^2$ and 4.3^2 GeV^2 , which are often considered as the energy scale of the processes involving heavy quarks. The χ^2 obtained for 205 data points for $F_2^\gamma(x, Q^2)$ is equal to 406, for both fitted and parametrized distributions.

The final parton densities in the real photon are (we skip the superscript γ in this part):

$$\begin{aligned} G(x, Q^2) &= G_{\text{pl}}(x, Q^2) + G_{\text{had}}(x, Q^2), \\ d(x, Q^2) &= d_{\text{pl}}(x, Q^2) + \frac{1}{2}v(x, Q^2) + \zeta(x, Q^2), \\ u(x, Q^2) &= u_{\text{pl}}(x, Q^2) + \frac{1}{2}v(x, Q^2) + \zeta(x, Q^2), \\ s(x, Q^2) &= s_{\text{pl}}(x, Q^2) + \zeta(x, Q^2), \\ c(x, Q^2) &= c_{\text{pl}}(x, Q^2) + c_{\text{had}}(x, Q^2), \\ b(x, Q^2) &= b_{\text{pl}}(x, Q^2) + b_{\text{had}}(x, Q^2). \end{aligned} \quad (\text{A2})$$

Note that all our densities describe the massless partons, although the kinematical constraints for c - and b -quarks were taken into account. The formulas given in the Appendix parametrizing densities of both heavy quarks represent the densities as included in the second sum in Eq. (22), that means that, for instance, the final density $b(x, Q^2)$ should be understood as being equivalent to $b[\chi_h(x, Q^2), Q^2]$.

A FORTRAN code of the parametrization can be obtained from the web pages [59]. The program includes also an option for the $F_2^\gamma(x, Q^2)$ calculation according to Eq. (22).

1. Pointlike part

We use the following form for the parametrization of the pointlike distribution for light quarks and gluons [denoted by $f_{\text{pl}}(x, Q^2)$]

$$\begin{aligned} \frac{1}{\alpha} x f_{\text{pl}}(x, Q^2) &= \frac{9}{4\pi} \ln \frac{Q^2}{(0.221 \text{ GeV})^2} \\ &\times \left[s^\alpha x^a (A + B\sqrt{x} + Cx^b) + s^{\alpha'} \right. \\ &\times \exp \left(-E + \sqrt{E' s^\beta \ln \frac{1}{x}} \right) \left. \right] (1-x)^D. \end{aligned} \quad (\text{A3})$$

For the gluon density G_{pl} :

$$\begin{aligned} \alpha &= -0.43865, \quad \alpha' = 2.7174, \quad \beta = 0.36752, \\ A &= 0.086893 - 0.34992s, \\ B &= 0.010556 + 0.049525s, \\ C &= -0.099005 + 0.34830s, \\ D &= 1.0648 + 0.143421s, \\ E &= 3.6717 + 2.5071s, \quad E' = 2.1944 + 1.9358s, \\ a &= 0.23679 - 0.11849s, \\ b &= -0.19994 + 0.028124s. \end{aligned} \quad (\text{A4})$$

For the up-quark density u_{pl} :

$$\begin{aligned} \alpha &= -1.0711, \quad \alpha' = 3.1320, \quad \beta = 0.69243, \\ A &= -0.058266 + 0.20506s, \\ B &= 0.0097377 - 0.10617s, \\ C &= -0.0068345 + 0.15211s, \\ D &= 0.22297 + 0.013567s, \\ E &= 6.4289 + 2.2802s, \quad E' = 1.7302 + 0.76997s, \\ a &= 0.87940 - 0.110241s, \quad b = 2.6878 - 0.040252s. \end{aligned} \quad (\text{A5})$$

For the down- and strange-quark densities, $d_{\text{pl}} = s_{\text{pl}}$:

$$\begin{aligned} \alpha &= -1.1357, \quad \alpha' = 3.1187, \quad \beta = 0.66290, \\ A &= 0.098814 - 0.067300s, \\ B &= -0.092892 + 0.049949s, \end{aligned}$$

$$C = -0.0066140 + 0.020427s, \quad (\text{A6})$$

$$D = -0.31385 - 0.0037558s,$$

$$E = 6.4671 + 2.2834s, \quad E' = 1.6996 + 0.84262s,$$

$$a = 11.777 + 0.034760s, \quad b = -11.124 - 0.20135s.$$

In the case of heavy quarks a slightly modified function h_{pl} was applied:

$$\begin{aligned} \frac{1}{\alpha} x h_{\text{pl}}(x, Q^2) &= \frac{9}{4\pi} \ln \frac{Q^2}{(0.221 \text{ GeV})^2} \\ &\times \left[s^\alpha y^a (A + B\sqrt{y} + Cy^b) + s^{\alpha'} \right. \\ &\times \exp \left(-E + \sqrt{E' s^\beta \ln \frac{1}{x}} \right) \left. \right] (1-y)^D, \end{aligned} \quad (\text{A7})$$

with $y = x + 1 - Q^2/(Q^2 + 6.76 \text{ GeV}^2)$ for the c -quark and $y = x + 1 - Q^2/(Q^2 + 73.96 \text{ GeV}^2)$ for the b -quark densities.

For the c -quark density c_{pl} , for $Q^2 \leq 10 \text{ GeV}^2$:

$$\begin{aligned} \alpha &= 2.9808, \quad \alpha' = 28.682, \quad \beta = 2.4863, \\ A &= -0.18826 + 0.13565s, \quad B = 0.18508 - 0.11764s, \\ C &= -0.0014153 - 0.011510s, \\ D &= -0.48961 + 0.18810s, \\ E &= 0.20911 - 2.8544s + 14.256s^2, \\ E' &= 2.7644 + 0.93717s, \quad a = -7.6307 + 5.6807s, \\ b &= 394.58 - 541.82s + 200.82s^2. \end{aligned} \quad (\text{A8})$$

For the c -quark density c_{pl} , for $Q^2 > 10 \text{ GeV}^2$:

$$\begin{aligned} \alpha &= -1.8095, \quad \alpha' = 7.9399, \quad \beta = 0.041563, \\ A &= -0.54831 + 0.33412s, \\ B &= 0.19484 + 0.041562s, \\ C &= -0.39046 + 0.37194s, \\ D &= 0.12717 + 0.059280s, \\ E &= 8.7191 + 3.0194s, \quad E' = 4.2616 + 0.73993s, \\ a &= -0.30307 + 0.29430s, \quad b = 7.2383 - 1.5995s. \end{aligned} \quad (\text{A9})$$

For the b -quark density b_{pl} , for $Q^2 \leq 100 \text{ GeV}^2$:

$$\begin{aligned} \alpha &= 2.2849, \quad \alpha' = 6.0408, \quad \beta = -0.11577, \\ A &= -0.26971 + 0.17942s, \end{aligned}$$

$$\begin{aligned}
B &= 0.27033 - 0.18358s + 0.0061059s^2, \\
C &= 0.0022862 - 0.0016837s, \\
D &= 0.30807 - 0.10490s, \quad E = 14.812 - 1.2977s, \\
E' &= 1.7148 + 2.3532s + 0.053734\sqrt{s}, \\
a &= 3.8140 - 1.0514s, \quad b = 2.2292 + 20.194s.
\end{aligned} \tag{A10}$$

For the b -quark density b_{pl} , for $Q^2 > 100 \text{ GeV}^2$:

$$\begin{aligned}
\alpha &= -5.0607, \alpha' = 16.590, \beta = 0.87190, \\
A &= -0.72790 + 0.36549s, \\
B &= -0.62903 + 0.56817s, \\
C &= -2.4467 + 1.6783s, \\
D &= 0.56575 - 0.19120s, \\
E &= 1.4687 + 9.6071s, \quad E' = 1.1706 + 0.99674s, \\
a &= -0.084651 - 0.083206s, \\
b &= 9.6036 - 3.4864s.
\end{aligned} \tag{A11}$$

2. Hadronlike part

We use a simple formula for the valence-quark density:

$$\frac{1}{\alpha} x v(x, Q^2) = A x^a (1 + B \sqrt{x} + Cx)(1-x)^D, \tag{A12}$$

with the following parameters:

$$\begin{aligned}
A &= 1.0898 + 0.38087s, \quad B = 0.42654 - 1.2128s, \\
C &= -1.6576 + 1.7075s, \quad D = 0.96155 + 1.8441s, \\
a &= 0.78391 - 0.068720s.
\end{aligned} \tag{A13}$$

For the gluon distribution, we apply

$$\begin{aligned}
\frac{1}{\alpha} x G_{\text{had}}(x, Q^2) &= \left[x^a (A + B \sqrt{x} + Cx) + s^\alpha \exp \right. \\
&\quad \left. \times \left(-E + \sqrt{E' s^\beta \ln \frac{1}{x}} \right) \right] (1-x)^D,
\end{aligned} \tag{A14}$$

with

$$\begin{aligned}
\alpha &= 0.59945, \quad \beta = 1.1285, \\
A &= -0.19898 + 0.57414s, \\
B &= 1.9942 - 1.8306s,
\end{aligned}$$

$$\begin{aligned}
C &= -1.9848 + 1.4136s, \\
D &= 0.21294 + 2.7450s, \\
E &= 1.2287 + 2.4447s, \\
E' &= 4.9230 + 0.18526s, \\
a &= -0.34948 + 0.47058s, \\
b &= 1.0012 + 0.99767s.
\end{aligned} \tag{A15}$$

In the case of the sea-quark density, we use:

$$\begin{aligned}
\frac{1}{\alpha} x \zeta(x, Q^2) &= \frac{s^\alpha}{\ln^a \frac{1}{x}} (1 + A \sqrt{x} + Bx) \\
&\quad \times \exp \left(-E + \sqrt{E' s^\beta \ln \frac{1}{x}} \right) (1-x)^D,
\end{aligned} \tag{A16}$$

with

$$\begin{aligned}
\alpha &= 0.71660, \quad \beta = 1.0497, \\
A &= 0.60478 + 0.036160s, \\
B &= 4.2106 - 0.85835s, \\
D &= 4.1494 + 0.34866s, \\
E &= 4.5179 + 1.9219s, \\
E' &= 5.2812 - 0.15200s, \\
a &= 0.72289 - 0.21562s.
\end{aligned} \tag{A17}$$

Finally, for the heavy-quark densities:

$$\begin{aligned}
\frac{1}{\alpha} x h_{\text{had}}(x, Q^2) &= \frac{s^\alpha}{\ln^a \frac{1}{x}} (1 + A \sqrt{y} + By) \\
&\quad \times \exp \left(-E + \sqrt{E' s^\beta \ln \frac{1}{x}} \right) (1-y)^D,
\end{aligned} \tag{A18}$$

with

$$y = x + 1 - \frac{Q^2}{Q^2 + 6.76 \text{ GeV}^2}$$

for c -quark and

$$y = x + 1 - \frac{Q^2}{Q^2 + 73.96 \text{ GeV}^2}$$

for b -quark. For the c -quark density c_{had} , for $Q^2 \leq 10 \text{ GeV}^2$:

$$\begin{aligned}\alpha &= 5.6729, \beta = 1.4575, \\ A &= -2586.4 + 1910.1s, \quad B = 2695.0 - 1688.2s, \\ D &= 1.5146 + 3.1028s, \quad E = -3.9185 + 11.738s, \quad (A19) \\ E' &= 3.6126 - 1.0291s, \quad a = 1.6248 - 0.70433s.\end{aligned}$$

For the c -quark density c_{had} , for $Q^2 > 10 \text{ GeV}^2$:

$$\begin{aligned}\alpha &= -1.6470, \beta = 0.72738, \\ A &= -2.0561 + 0.75576s, \quad B = 2.1266 + 0.66383s, \\ D &= 3.0301 - 1.7499s + 1.6466s^2 \\ E &= 4.1282 + 1.6929s - 0.26292s^2, \quad (A20) \\ E' &= 0.89599 + 1.2761s - 0.15061s^2,\end{aligned}$$

$$a = -0.78809 + 0.90278s.$$

For the b -quark density b_{had} , for $Q^2 \leq 100 \text{ GeV}^2$:

$$\begin{aligned}\alpha &= -10.210, \beta = -2.2296, \\ A &= -99.613 + 171.25s, \quad B = 492.61 - 420.45s, \\ D &= 3.3917 + 0.084256s, \quad E = 5.6829 - 0.23571s, \quad (A21) \\ E' &= -2.0137 + 4.6955s, \quad a = 0.82278 + 0.081818s.\end{aligned}$$

For the b -quark density b_{had} , for $Q^2 > 100 \text{ GeV}^2$:

$$\begin{aligned}\alpha &= 2.4198, \beta = 0.40703, \\ A &= -2.1109 + 1.2711s, \quad B = 9.0196 - 3.6082s, \\ D &= 3.6455 - 4.1353s + 2.3615s^2, \quad (A22) \\ E &= 4.6196 + 2.4212s, \quad E' = 0.66454 + 1.1109s, \\ a &= -0.98933 + 0.42366s + 0.15817s^2.\end{aligned}$$

[25] The Q^2 -dependence will appear back in the final solution, in both α_s and G^γ , where it is then a correction of higher order in α_s .
[26] In our analysis we take the variable χ_h instead of x in front of the bracket in the last sum on Eq. (22). The fit (χ^2 value) agrees with the fit based on Eq. (22) at the percent level. At the same time the value of F_2^γ around thresholds is shifted by up to $\sim 10\%$; also changing the form of the positivity constraint leads to changes of F_2^γ in this region of similar size. Other subtraction terms and positivity constraints are under study and will be presented in a future publication.
[27] Which means that any further $x \rightarrow \chi_h$ substitution is not needed.
